

ExampleSpeakerStructural bioinformatics Project – Assignment 1: Understanding protein function.

Chaperones are a group of proteins that play a crucial role in protein folding, stability, and function within cells. The High Shock Proteins (HSP) are part of the chaperone protein family, they play a key role in making sure other proteins fold properly, especially when cells are under stress, like in high temperatures. These proteins are similar across different species, highlighting their importance. They work using ATP (a kind of cellular energy currency) to bind and release other proteins, ensuring these proteins maintain their correct 3D shape. This is crucial because misfolded proteins can lead to a variety of diseases. To sum up, HSP are like a quality control manager in a cell, keeping proteins in shape and the cell healthy.

Purple

Chaperone Family	Topology of Binding	Co-chaperone	Known Function
Hsp100		ClpP, SspB, Hsp70, Hsp40	<ul style="list-style-type: none"> • Works with DnaK in ATP-dependent disaggregation and proteolysis • Prevents aggregation, degradation and turnover of unassembled mitochondrial proteins • Reactivates heat-damaged proteins • Establishes and maintains prion phenotype in yeast
Hsp90		Hop, Hip, Hsp70, Immunophilins, Grp78	<ul style="list-style-type: none"> • Refolds proteins in stressed cells. Probable secretory chaperone in prokaryotes • Major cytosolic chaperone in eukaryotes. • Cytoprotection and intracellular signaling • In ER, controls protein homeostasis, folding and assembly of secretory proteins
Hsp70		Hsp40, GrpE	<ul style="list-style-type: none"> • Ubiquitous Principal folding chaperone • Works with ClpB as disaggregase • Folding of newly synthesized proteins • Protein transport into ER and mitochondria
Hsp60 (Group I)		Hsp10	<ul style="list-style-type: none"> • Major chaperone for protein folding in prokaryotes • Stabilizes proteins during heat stress • Promotes folding of over-produced proteins • Major chaperone in mitochondria and chloroplast
Hsp60 (Group II)		Prefoldin/GimC	<ul style="list-style-type: none"> • Promotes folding of a cytosolic proteins in eukaryotes • Refolding of unfolded polypeptides in vitro
sHsps		-	<ul style="list-style-type: none"> • Stabilizes unfolded polypeptides • Prevents aggregation • Works with Hsp70 in protein refolding • Structural protein of eye lens

Once

1. What is the function of your protein? Is the same for the whole protein family?

HSP90, an essential member of the chaperone protein family, goes beyond just assisting in protein folding under stress like high temperatures. It's integral to various cellular processes, including cell cycle control, signal transduction, and mitochondrial import, maintaining the stability and function of diverse client proteins. Working through a dynamic cycle with ATP, HSP90 interacts with co-chaperones and client proteins, ensuring they achieve their correct 3D structure. This role is vital in preventing diseases caused by misfolded proteins and is conserved across species. Essentially, HSP90 acts as a versatile quality control manager in the cell, adapting to different needs and conditions to keep the cellular machinery running smoothly.

Each HSP90 protein may have unique co-chaperones and client proteins, leading to different roles in cellular processes like signal transduction, protein trafficking, immune response, and stress response.

Thus, while the core function of assisting in protein folding is conserved across the family, the details of their activity can vary significantly.

2. How is able to carry out this function?

HSP90, a molecular chaperone, carries out its function through an ATP-dependent process, essential for its chaperoning activity. It binds to partially folded or unfolded protein substrates, preventing aggregation and guiding them towards their native state. This is achieved by cycling between ATP-bound and ADP-bound states, which induces conformational changes in HSP90. These changes are crucial for the folding, stabilization, and activation of its client proteins, ensuring they achieve their correct functional forms and contribute to cellular health, especially under stress conditions.

3. Does your protein require the interaction with other proteins or molecules to carry out this function?

HSP90's function crucially depends on interactions with co-chaperones and various proteins, including Hsp70, p23, and Hop, which modulate its activity and substrate specificity. These co-chaperones, along with other interacting proteins, play a pivotal role in regulating HSP90's ATPase cycle and determining the specific client proteins it assists. The client proteins, which are the direct beneficiaries of HSP90's chaperoning activity, further underscore its versatility and importance in cellular processes, from maintaining protein stability to facilitating stress responses.

4. What is the fold of your protein? Is this the same fold for the other proteins of the family?

The signature pattern for the hsp90 family of proteins is located in a highly conserved region found in the N-terminal part of these proteins.

As we can see it is relevant for the family since these domains are shared between them.
